

ABSTRACT OF THE DISCLOSURE

A device that can be used, for example, for application or use with hair care products. The device includes two sheets connected to one another by a connecting region which defines a cavity on a first side of the connecting region, such that a user's hand can be inserted into the cavity. A flexible strip preferably cut into fringes and flaps, is provided on a second side of the connecting region. A method for manufacturing a device of this kind is also provided in which two webs of strip material are unrolled simultaneously, connected, and then cut. Parts of the webs, including both the connecting region and the cut fringes and flaps, are then separated. The device can optionally be impregnated with a product, for example, a hair care product.
